Clean air solutions
CORROSION CONTROL

SENSITIVE ELECTRONICS

Automation is used in manufacturing businesses around the world. Many industries are completely reliant on electronic and electrical control equipment for the safe and efficient operation of complex and valuable manufacturing processes. In certain heavy industries, the external air around the facility is likely to be contaminated with acidic gases.

These gases originate from the raw materials used in the process or chemicals added to the process. The industries where these gases are most prevalent are: oil and gas, pulp and paper, mining and metal refining and waste water treatment.

At oil and gas facilities, the acidic gases arise from sulphur impurities present in crude oil. At pulp and paper facilities, the contaminants arise from chemicals used to digest and bleach wood and other cellulose based materials for the pulp making process.

Examples of acidic gases include hydrogen sulphide (H₂S), sulphur dioxide and sulphur trioxide (SO₂, SO₃), chlorine (Cl₂), nitrogen oxides (NOₓ) and hydrogen fluoride (HF). All of these gases are corrosive towards electronic and electrical control equipment.

If steps are not taken to protect the control assets then the likely consequence will be unscheduled breakdown caused by equipment failure. Process downtime is expensive and erodes profit and maintenance budgets.

The degradation of electrical control equipment by corrosive gases is a well-known effect. In fact, virtually all manufacturers of sensitive electronic/electrical equipment specify the required environmental conditions for their equipment as part of the warranty conditions. These specifications set limits for temperature, relative humidity and chemical contaminants as they all influence the rate of corrosion.

Many individual electronic components are afforded some protection from corrosive agents due to the fact they are encapsulated inside an air tight plastic or resin body. The components that are most susceptible to damage are printed circuit boards (PCBs), exposed contacts and conductors.

There are several established techniques for PCB production. They differ in terms of cost, surface flatness, shelf life and corrosion resistance. The method that is gaining most popularity following the introduction of RoHS legislation (restriction of hazardous substances) which required the elimination of lead from solder is “Immersion Silver” (iAg or IM Ag). In this method, the copper tracks on the PCB are coated with a thin layer of silver (< 0.25 microns) prior to adding the on-board components. However, the exposed edges of the copper sub-track and the silver coating are susceptible to corrosion.

Molecular filtration using adsorption techniques is the industry accepted method to remove the corrosive agents from the air. Although the standard indicates concentrations of individual gases that loosely correspond to the 4 classes of corrosivity, these have to be treated with caution. If multiple gases are present in the air, then there may be a synergistic effect on the observed rate of corrosion that is difficult to quantify. As a consequence, on-site monitoring for a single or multiple gases may not in itself predict or explain the corrosivity, these have to be treated with caution. If multiple gases are present in the air, then there may be a synergistic effect on the observed rate of corrosion that is difficult to quantify. As a consequence, on-site monitoring for a single or multiple gases may not in itself predict or explain the corrosivity that to reduce gas concentrations from ppm levels down to very low ppb levels will require very high efficiency molecular filtration. It can be readily understood that to reduce gas concentrations from ppm levels down to very low ppb levels will require very high efficiency molecular filtration and devices that are not compromised by internal leaks or bypasses.

There are two commonly referenced standards that categorise environmental conditions in relation to the deployment and reliability of electronic equipment:

1. ANSI/ISA-71.04-2013.
2. IEC 60721-3-3

ANSI/ISA-71.04-2013 is the most popular and focuses on airborne contaminants and observed rates of corrosion for copper and silver metals. IEC 60721-3-3 categorises environmental conditions based on several parameters such as climatic conditions, biological and chemical contaminants and mechanical effects.

ANSI/ISA-71.04-2013 defines 4 classes of air quality that relate to different rates of reactivity or corrosion of copper and silver. These are: G1 Mild, G2 Moderate, G3 Harsh and GX Severe. Most original equipment manufacturers require provision of G1 Mild conditions as part of their warranty conditions since the standard states for class G1 that “Corrosion is not a factor in determining equipment reliability”. The external ambient air at some heavy process industries will routinely be classified as GX Severe.

For reference, the standard tabulates concentrations of different gases that approximately correspond to the 4 categories of copper reactivity. It is worth noting that extremely low concentrations of some agents are required to achieve G1 Mild conditions. For example, at relative humidity < 50%, the concentration of hydrogen sulphide should be < 3 parts per billion (ppb) to achieve G1 conditions and the concentration only needs to rise to > 50 ppb for GX conditions to be achieved. It is known that external ambient levels of hydrogen sulphide in the air at some industrial facilities are likely to exceed 1 part per million (ppm).

There are several established techniques to remove the corrosive agents from the air. The information above defines the requirement for effective molecular filtration. It can be readily understood that to reduce gas concentrations from ppm levels down to very low ppb levels will require very high efficiency molecular filtration and devices that are not compromised by internal leaks or bypasses.
MOLECULAR FILTRATION
SOLUTIONS OVERVIEW

Rooms where electrical and electronic control equipment are installed are ventilated with temperature and humidity conditioned air to achieve the environmental conditions required under the warranty conditions imposed by equipment manufacturers.

The supply or make-up air will be taken from an external location and in certain process industries that air may be heavily contaminated with harmful corrosive agents, e.g., acidic gases. If these gases are not removed before the air enters the room, then the control equipment will be susceptible to damage and ultimately failure due to corrosion.

The gases can be removed by molecular filtration. The gas concentrations in the inlet air may be high; perhaps tens of parts per million (ppm). However, the manufacturer’s warranty terms require in-room gas concentrations in the very low parts per billion (ppb) range. It is clear therefore that the filter must operate with very high efficiency on a one-pass basis.

The Camfil VDBs filter is specifically designed for this purpose. The make-up air, which may account for up to 40% of the total room ventilation rate is used to positively pressurise the control room to prevent the ingress of fugitive gases.

The level of pressurisation can be compromised by unnecessary opening of doors and windows, leaks dues to construction defects and leaks at service entry points. To provide additional protection from fugitive gases, additional molecular filtration can be installed in the return / recirculation air system.

Concentrations of gases are much lower in the return air and a filter will operate on a multi-pass basis. A lighter duty filtration solution than that used in the make-up air system will be appropriate. The Camfil PSSA housing fitted with CamCarb VG filter modules is intended for this specific application.

An alternative molecular filtration solution would use PSSA housings and Camcarb VG in both the supply and return air systems. The heavier duty VG300 modules should be selected for the supply air and lighter duty VG440 modules should be used in the return air.

This methodology can be used when external gas concentrations are considered to be low to moderate or intermittent in nature. To handle multiple gases or to provide an acceptable lifetime, it might be necessary to use more than 1 stage of VG300 modules in the supply air.

ALTERNATIVE CONTROL ROOM VENTILATION AND FILTRATION SYSTEM

Multi-stage PSSA housing with VG300 modules in supply air and PSSA housing with VG440 modules in the return air.
Molecular Filtration - Corrosion Control

PROCARB
MOLECULAR FILTRATION SOLUTIONS

The Camfil ProCarb family of molecular filters are designed for industrial applications and provides...

"The very highest levels of performance in those applications where plant reliability and elimination of corrosive gases, toxic gases and odours is essential for operational security and regulatory compliance."

Inherently leak-free design and construction, the appropriate filter media and extended contact time ensure the highest levels of removal efficiency and longest possible lifetime, even in single pass configurations handling high gas concentrations.

PROCARB VERTICAL DEEP BED FILTER (VDBs)

The VDBs filter is a robust solution for removing corrosive gases from supply (make-up) air systems with very high efficiency on a single pass basis. The filters contain vertical walls of molecular filtration media that are retained between perforated screens. The air passes horizontally through the filters.

A range of standard sizes accommodate flows from 1000 m³/h to 25,000 m³/h. Depending on the airflow, the filters may be configured with up to 3 separate media beds in series. This allows different medias to be combined in a layered configuration (not blended) to handle complex contaminant mixtures in the most cost-effective manner. Pre-and after-filters are easily incorporated in the filter housing to provide a total filtration solution in a single unit. VDBs filters are safe and simple to install. They are completely passive in operation and require little or no routine maintenance beyond changing the filters and media.

Fans and variable speed drives can be incorporated as options.

**PROCARB HORIZONTAL DEEP BED FILTER (HDB)**

The HDB filter is a robust solution for removing corrosive gases from make-up air systems with very high efficiency on a single pass basis. The filters contain horizontal beds of molecular filtration media that are retained on top of a horizontal perforated screen.

The air passes vertically through the media bed. The normal airflow direction is upward, but this arrangement can be reversed in some applications.

The filters utilise a very deep bed of media and they are particularly well suited to applications that combine low to moderate airflows and relatively high contaminant concentrations. A range of standard sizes accommodate flows from 500 m³/h to 5,000 m³/h. Pre- and after-filters can be incorporated by the addition of bolt-on housing to provide a total filtration solution.

HDB filters are safe and simple to install. They are completely passive in operation and require little or no routine maintenance beyond changing the filters and media. Fans and variable speed drives can be incorporated as options.

**FEATURES**
- Very long contact time to optimise media usage and lifetime
- Convenient gravity removal of spent media, easy to regulate media flow
- Can be used in conjunction with any filtration media (single or multiple layers)
- Air contact parts from 6061 T-6 aluminium or 316 grade stainless steel, depending on application
- Painted steel support frame
- Inherently leak-free design
- Media supported on 316 quality stainless steel screen
- Lifting points for fork lift truck
- Compact rectangular footprint for minimal use of plant room space

**BENEFITS**
- Confidence in high level protection for downstream equipment / environment
- No requirement for expensive vacuum equipment to change media
- Ability to target specific gas types
- Corrosion resistant
- Robust support
- Highly reliable performance
- Corrosion resistant
- Simple and safe to install, operate and maintain
- Minimum requirement for concrete or steel foundation

**FEATURES CUSTOMER BENEFITS**
- Positive filter clamping mechanism. No special tools required. Minimal leakage. Quick and easy filter changes.
- Aluminium coated steel construction
- Double skin with insulation
- May be used in multiple stages
- Minimal maintenance and service time
- No requirement to handle filter media
- Leakage tested housing

**CUSTOMER BENEFITS**
- Minimal leakage. Quick and easy filter changes.
- Offers a robust protection against environmental conditions with a good finish
- Internal temperature control, and reduced risk of condensation
- Ability to target multiple gases utilising different media
- Reduced maintenance cost and equipment downtime
- Reduced PPE requirement for installation and maintenance
- Ensure high efficiency of contaminant removal

**POSITIVE SEAL SIDE ACCESS HOUSING (PSSA)**

PSSA housings provide a high-integrity minimum leakage installation for CamCarb VG filter modules in applications where the protection of sensitive control equipment from corrosion caused by acidic gases is essential for the reliable operation of critical industrial processes.

To ensure the highest levels of efficiency and the longest possible lifetime, it is necessary that CamCarb VG modules are mounted in robust housings where an engineered approach is taken to eliminate internal leaks that would otherwise degrade performance.

As a first in the corrosion control industry, PSSA housings include a unique positive clamping mechanism to ensure leakage between the modules and the internal sealing frame is eliminated. The housings are designed to ensure ease of installation and simple servicing procedures.

Depending on the contaminant(s) to be controlled, virtually any molecular filtration media may be used in VG modules. 1, 2 or 3 PSSA housing can be used in series to handle mixed gases or to provide extended lifetime. The VG filters and housings are passive in operation and require minimal routine maintenance.

PSSA housings may be installed in supply and recirculation air systems. A range of standard size housings are available to provide airflow capacities ranging from 800 m³/h to 10,500 m³/h.
**CAMCARB VG MODULE**

These plastic filter modules are industry standard items. There are 2 standard configurations; VG 300 and VG440.

The VG300 format is best suited for moderate duty (normally make-up air) applications and the VG440 format is best suited to light duty (recirculation air) applications.

In many other manufacturers’ housings, this type of filter is known to have high mechanical leakage rates that will compromise the manufacturers claimed efficiency.

CamCarb VG filters should be used in Camfil PSSA housings where the unique clamping mechanism will eliminate the internal leaks. The modules may be filled with many different molecular filtration media to suit different gas challenges.

Camfil strongly recommend that when multiple medias are required, they are used in a layered arrangement rather than as a blended mixture.

The layered arrangement ensures the lowest possible total cost of ownership (life cycle costs) since each individual media can be changed when it reaches the end of useful life. With a blended media, all the media needs to be replaced when just a single component has failed.

**CAMCARB CG CYLINDER**

The CamCarb CG cylindrical filter is Camfil’s flagship molecular filter for moderate duty applications in process and industrial environments. When mounted on its dedicated holding frame, all internal leaks are eliminated and very high efficiency values are achieved. CamCarb CG is ideally suited to use in recirculation/return air systems in corrosion control applications. It can also be used in make-up air systems in applications where low or moderate gas concentrations are expected.

CamCarb CG is manufactured from plastic and is extremely corrosion resistance. The air-inlet endcap features a radused profile to reduce pressure drop and a pair of co-moulded TEP thermo-elastic gaskets to eliminate air by-pass. Each cylinder is filled using a vibratory technique to ensure perfect packing density of the filtration media. The cylinders are mounted and dismounted from the base plate using a standard 24 mm wrench.

**CAMCLEANER MOLECULAR**

The CamCleaner Molecular is a free-standing air cleaner designed for the removal of corrosive gases within control rooms at industrial sites.

The device is completely self-contained and includes pre-filtration, molecular filtration using CamCarb CG cylinders, after-filtration, a fan and controls. Clean air may be discharged at the top or the bottom of the unit depending on the configuration. Dampers allow the unit to be used in 100% fresh air recirculation mode, or in a combination of the two modes.

The CamCleaner Molecular is particularly useful if there is no external recirculation system and additional filtration is required to overcome the effect of ingress of fugitive gases.

The CamCleaner Molecular is quiet and has a high aesthetic finish. It is therefore also ideally suited to use in process control rooms with a high level of human occupancy. Nominal flow capacity is 1700 m³/h.
CAMPURE
MOLECULAR FILTRATION MEDIA

Achieving a cost effective molecular filtration solution is very dependent on selecting the most appropriate media for the application. It is necessary to take into account the target gases, temperature and relative humidity. It is equally important to ensure that sufficient media is deployed in the filter to ensure that a high efficiency value is maintained over an extended period and a low life cycle cost (LCC) or total cost of ownership (TCO) value is obtained.

There are many commercial adsorbents available to filter manufacturers, contractors, service companies and end users. Even to the trained eye many are visually indistinguishable. The reality is users. Even to the trained eye many are visually indistinguishable. The reality is that a high efficiency value is maintained over an extended period and a low life cycle cost (LCC) or total cost of ownership (TCO) value is obtained.

Camfil manufacture all their CamPure media for corrosion control applications in-house according to stringent QA procedures in an ultra-modern, purpose designed facility that uses the latest process control technologies. Performance testing is also undertaken in-house in Camfil’s unique molecular filtration test laboratory.

In this facility, media samples and full size filters can be mounted in a test duct and the airflow conditioned to mimic the customers’ application (temperature and relative humidity).

When the desired conditions are stable and the media has reached equilibrium with the airflow, gases or vapours can be injected upstream of the test piece at real-world concentrations that also mimic the customers application (typically low parts per million level).

Using extremely sensitive upstream and downstream real-time gas monitors, the efficiency of the filter is immediately revealed. This facility is capable of producing results from procedures in accordance with ISO 10121-1 / 10121-2 and ASHRAE 145.1 / 145.2.

ON-SITE PERFORMANCE MONITORING

The use of molecular filtration for the prevention of corrosion in electrical or electronic equipment is a critical application. The safe and reliable operation of end-user assets and processes are dependent on the performance of the molecular filters. Camfil provide customers with support services to monitor the on-going effectiveness of their filters.

Conceptually these involve; either monitoring the impact of the air quality in the enclosed space or monitoring the condition of the media in the filter.

The impact of the air quality is assessed by reactivity monitoring or measuring the rate of corrosion of copper and silver sensors. This can be done by either (i) a passive or (ii) a continuous real-time technique. The passive method involves exposing copper and silver foil coupons for 30 days inside the enclosed space (CamPure coupons).

The software is to provide “best estimates” of the performance of molecular filtration products under selectable conditions that closely approximate real applications. Predicting the performance of molecular filters in the real world is a complex issue. This software takes account of the key factors that affect the performance of molecular filters; the gas/vapour to be controlled, concentration, type of adsorbent, amount of adsorbent (contact time), and temperature.

The software has been developed using adsorption theory, many years application knowledge, field measurements and results of extensive product testing in Camfil’s unique molecular filtration test rig.
Camfil offer the latest advanced technology real-time corrosion sensor: ISA-Check II.

This entirely new product has been developed specifically for use in heavy process industries and offers some unique customer benefits.

Real-time information on the air corrosivity is crucial for effective corrosion protection of valuable control assets. ISA-Check II measures and registers the change over time in the electrical resistance (ER) of a thin metal track applied on an insulating substrate. If the metal corrodes, the cross-sectional area of the track decreases and the ER increases. The changes in ER can be directly translated into corrosion depth and corrosion rate.

The ISA-Check II monitoring system is comprised of four principal parts:

- Electronic logger for measuring and recording ER
- Sensitive thin-film metal corrosion sensors
- Non-contact communication interface between the logger and computer, the “data pencil”
- User-friendly software programme, WINISACHECK

Camfil – a global leader in air filters and clean air solutions

For more than half a century, Camfil has been helping people breathe cleaner air. As a leading manufacturer of premium clean air solutions, we provide commercial and industrial systems for air filtration and air pollution control that improve worker and equipment productivity, minimize energy use, and benefit human health and the environment.

We firmly believe that the best solutions for our customers are the best solutions for our planet, too. That's why every step of the way – from design to delivery and across the product life cycle – we consider the impact of what we do on people and on the world around us. Through a fresh approach to problem-solving, innovative design, precise process control and a strong customer focus we aim to conserve more, use less and find better ways – so we can all breathe easier.

The Camfil Group is headquartered in Stockholm, Sweden, and has 30 manufacturing sites, six R&D centres, local sales offices in 30 countries, and 4,500 employees and growing. We proudly serve and support customers in a wide variety of industries and in communities across the world. To discover how Camfil can help you to protect people, processes and the environment.
